

# Error Analysis of GPS estimates

## Lecture 06

Thomas Herring

[tah@mit.edu](mailto:tah@mit.edu)

# Issues in GPS Error Analysis

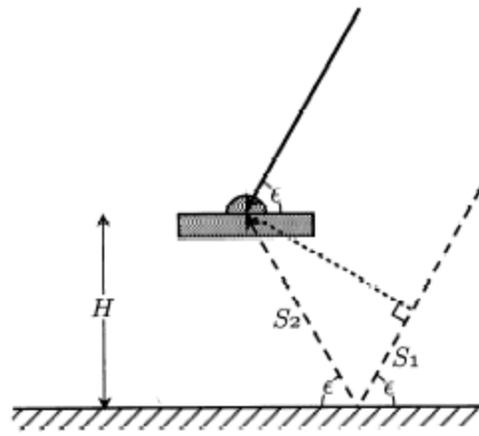

- What are the sources of the errors ?
- How much of the error can we remove by better modeling ?
- Do we have enough information to infer the uncertainties from the data ?
- What mathematical tools can we use to represent the errors and uncertainties ?

# Determining the Uncertainties of GPS Parameter Estimates

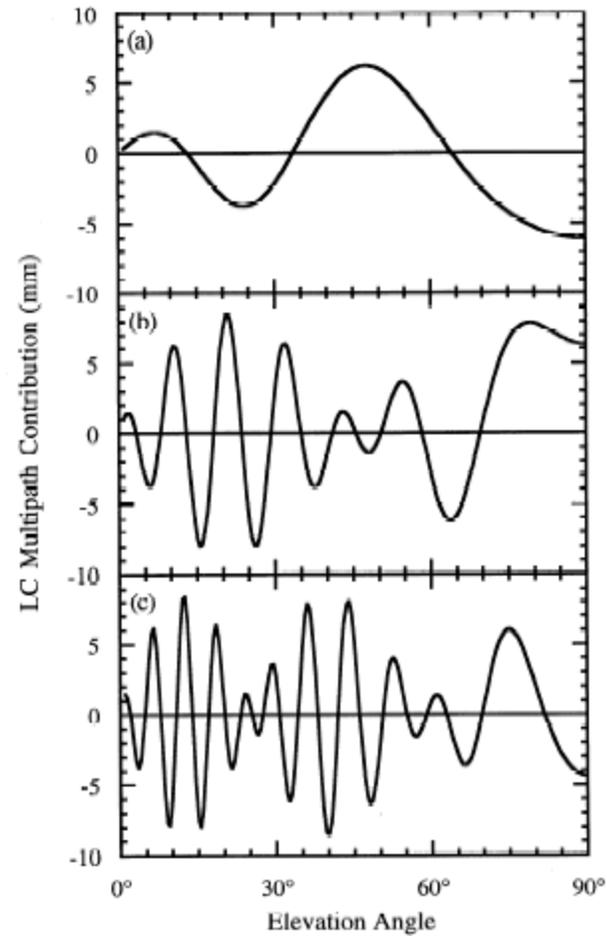

- Rigorous estimate of uncertainties requires full knowledge of the error spectrum—both temporal and spatial correlations (never possible)
- Sufficient approximations are often available by examining time series (phase and/or position) and reweighting data
- Whatever the assumed error model and tools used to implement it, external validation is important

# Sources of Error

- Signal propagation effects
  - Receiver noise
  - Ionospheric effects
  - Signal scattering ( antenna phase center / multipath )
  - Atmospheric delay (mainly water vapor)
- Unmodeled motions of the station
  - Monument instability
  - Loading of the crust by atmosphere, oceans, and surface water
- Unmodeled motions of the satellites

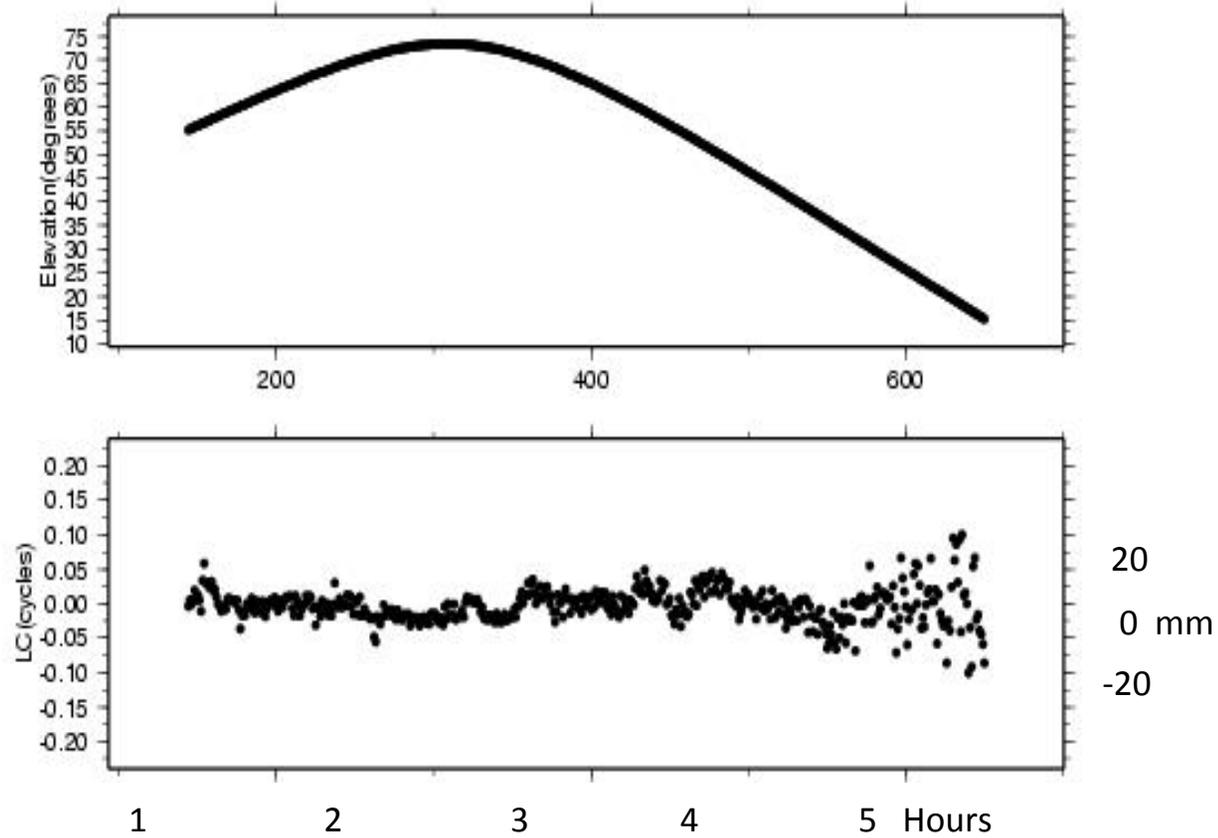

Simple geometry for incidence of a direct and reflected signal

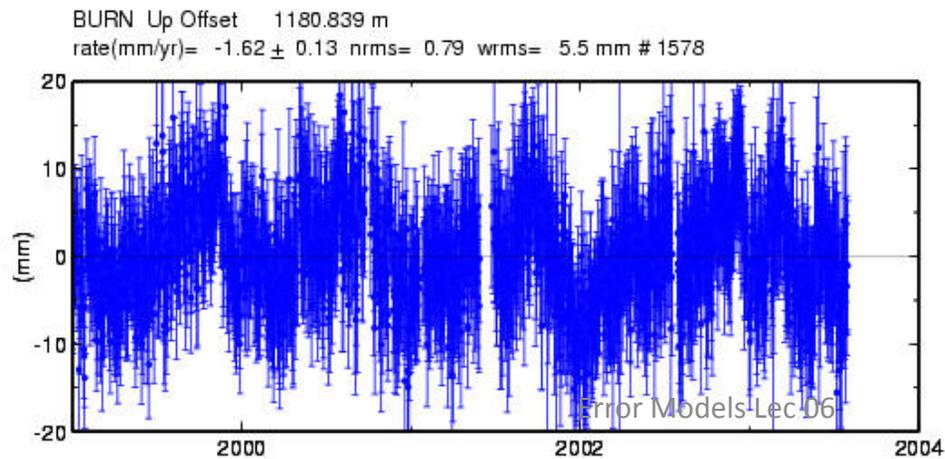

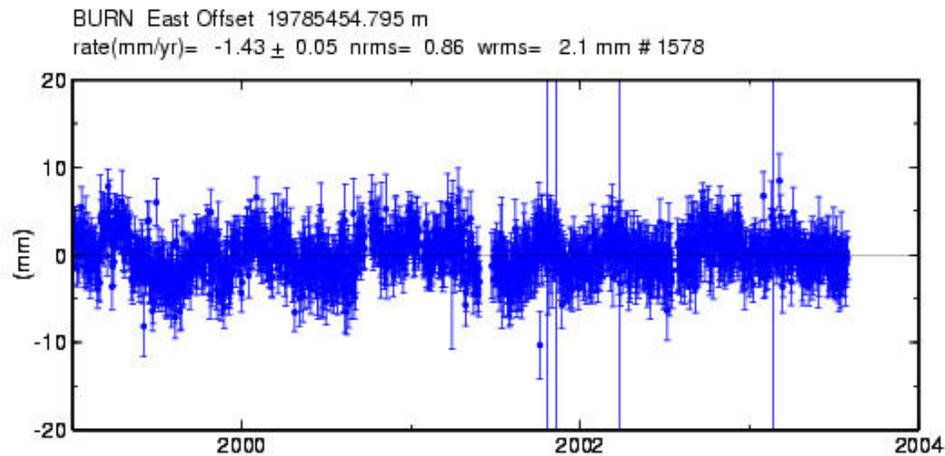

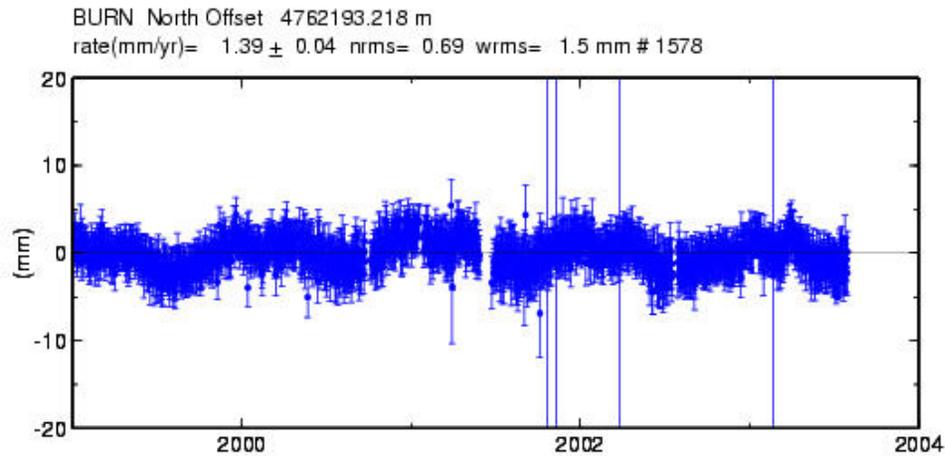

Multipath contributions to observed phase for an antenna at heights (a) 0.15 m, (b) 0.6 m, and (c) 1 m. [From *Elosegui et al*, 1995]

# Characterizing Phase Noise

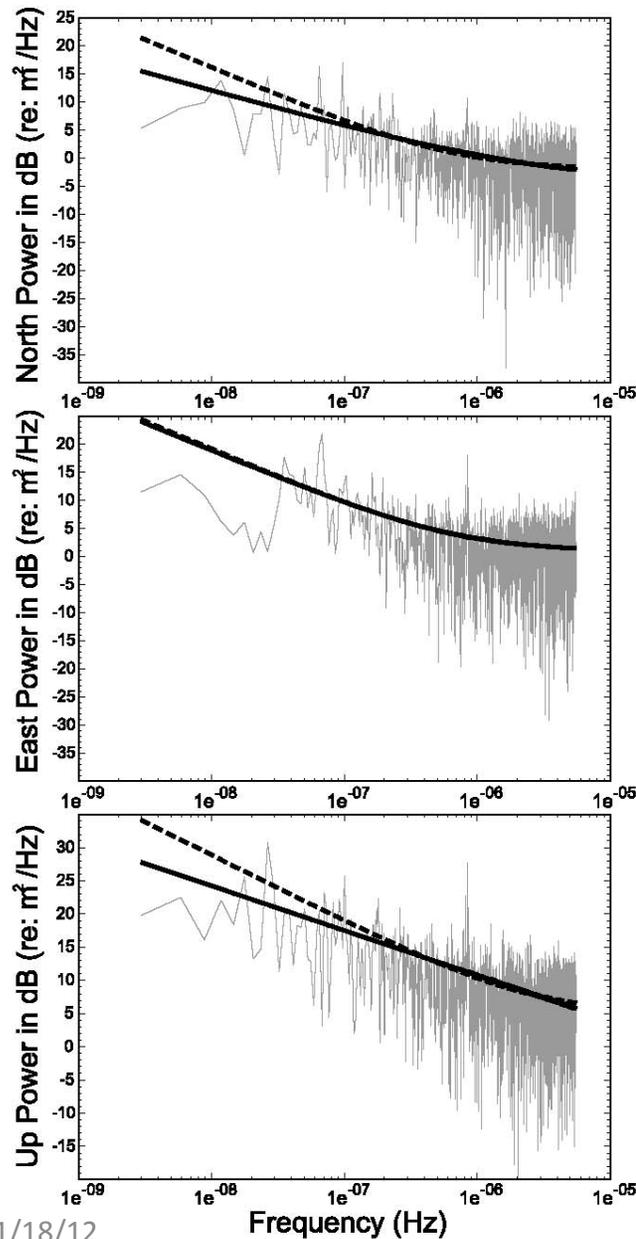

Elevation angle and phase residuals for single satellite

## Characterizing the Noise in Daily Position Estimates

Note temporal correlations of 30-100 days and seasonal terms

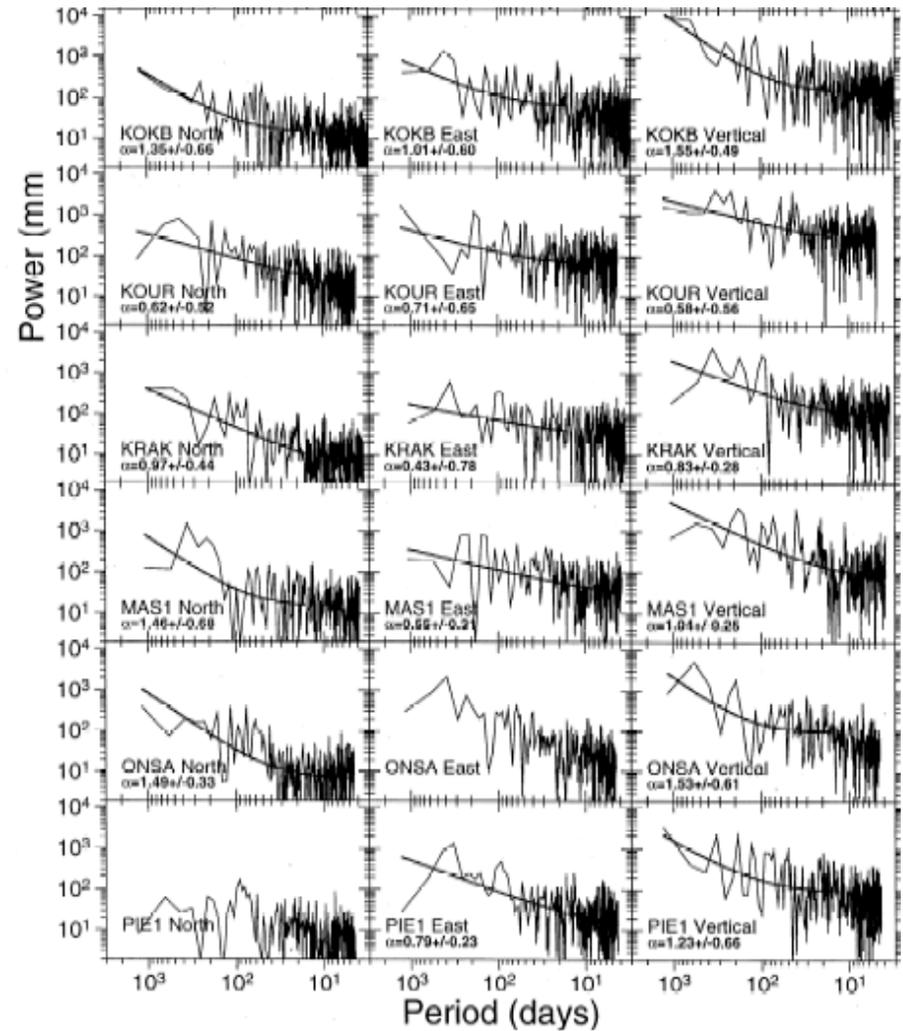

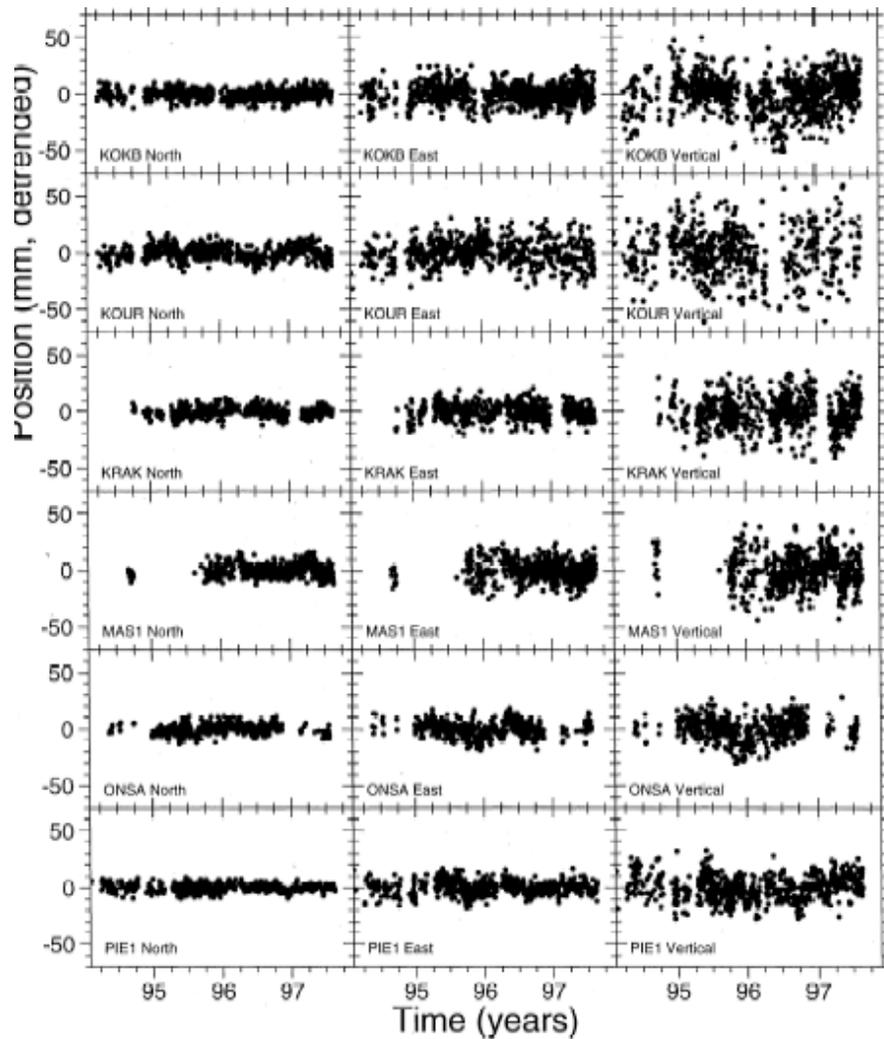

## Spectral Analysis of the Time Series to Estimate an Error Model

Figure 5 from *Williams et al* [2004]: Power spectrum for common-mode error in the SOPAC regional SCIGN analysis. Lines are best-fit WN + FN models (solid=mean ampl; dashed=MLE)

Note lack of taper and misfit for periods > 1 yr

# . . . spectral analysis approach

- Power law: slope of line fit to spectrum
  - 0 = white noise
  - -1 = flicker noise
  - -2 = random walk
- Non-integer spectral index (e.g. “fraction white noise”  $\rightarrow 1 > k > -1$  )
- Good discussion in Williams [2003]
- Problems:
  - Computationally intensive
  - No model captures reliably the lowest-frequency part of the spectrum

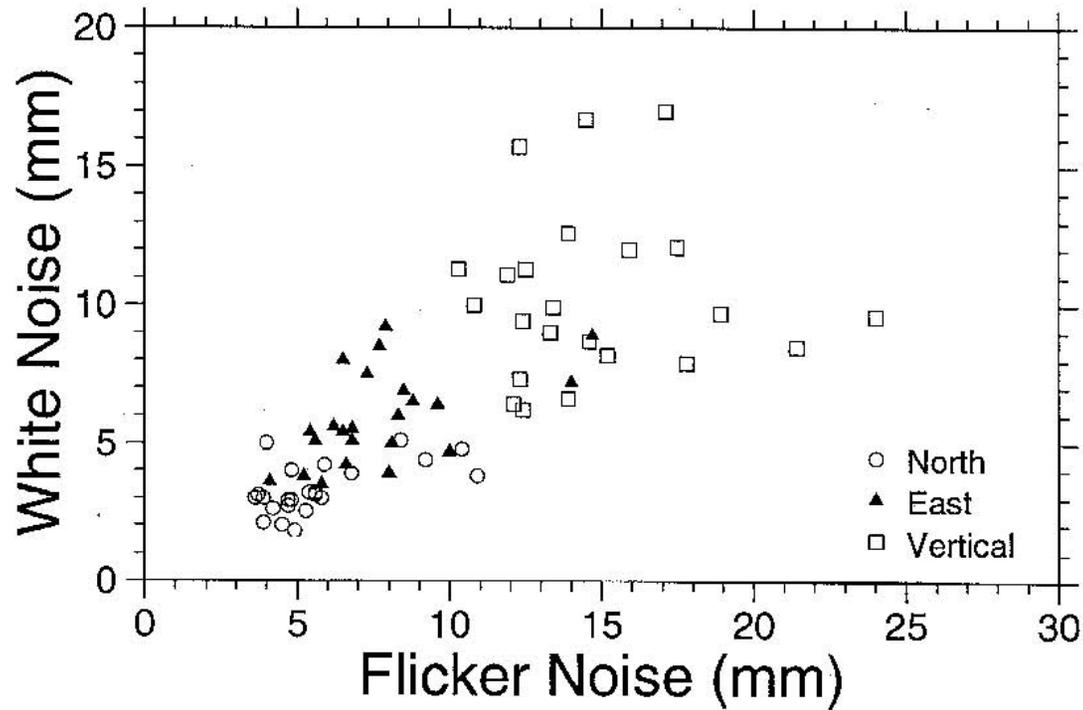

## Examples of times series and spectra for global stations

From Mao *et al.*, 1999

11/18/12

Short-cut: Use white noise statistics ( wrms) to predict the flicker noise

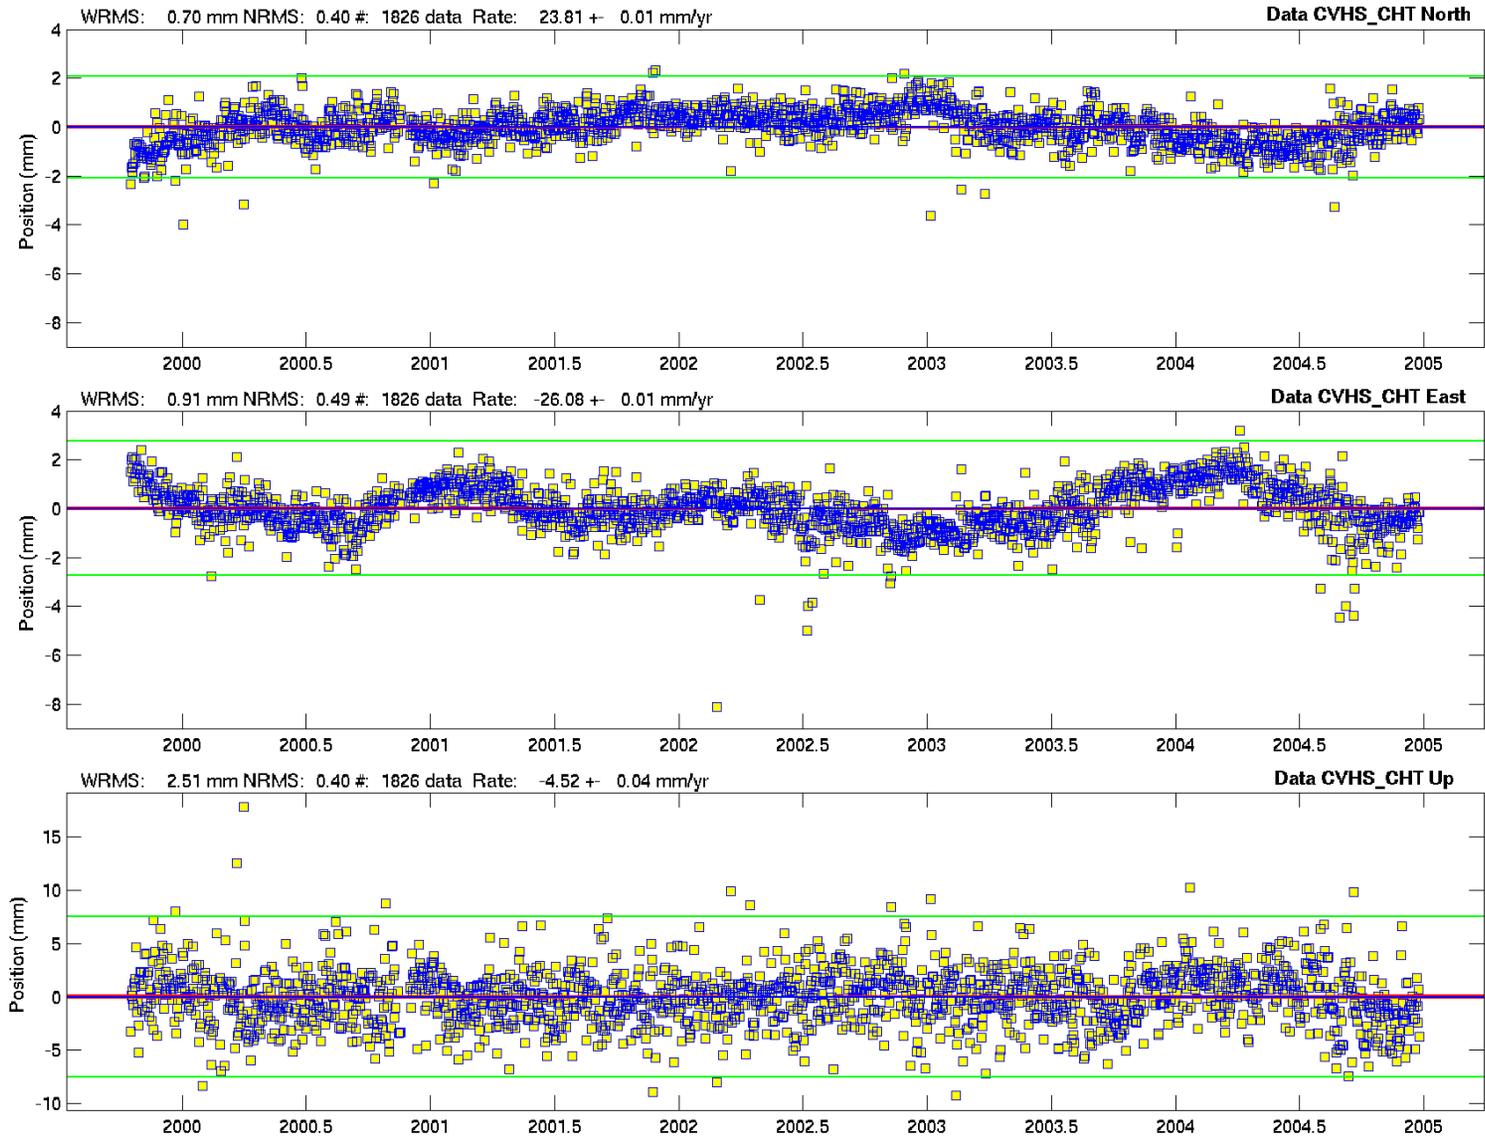

White noise vs flicker noise from *Mao et al.* [1999] spectral analysis of 23 global stations

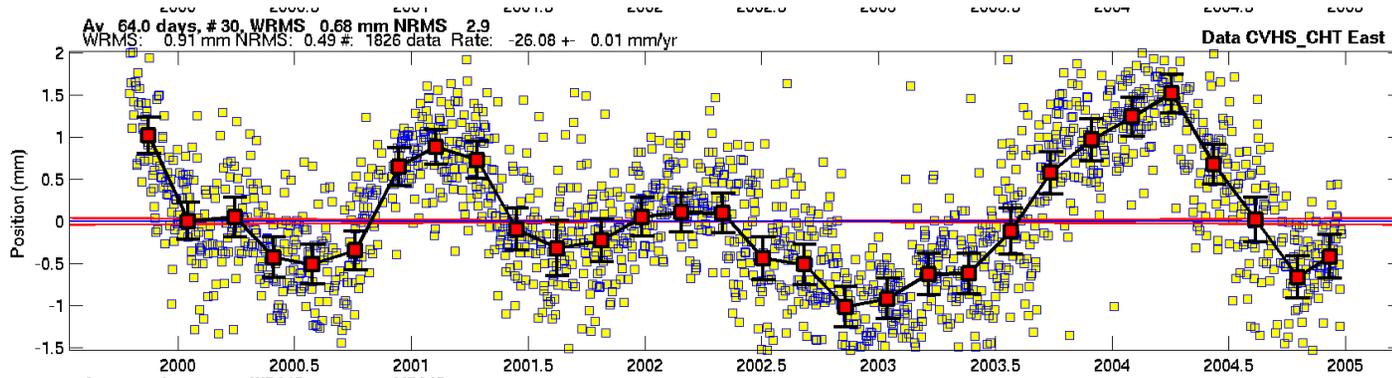

# “Realistic Sigma” Algorithm for Velocity Uncertainties

- Motivation: computational efficiency, handle time series with varying lengths and data gaps; obtain a model that can be used in globk
- Concept: The departure from a white-noise ( $\sqrt{n}$ ) reduction in noise with averaging provides a measure of correlated noise.
- Implementation:
  - Fit the values of  $\chi^2$  vs averaging time to the exponential function expected for a first-order Gauss-Markov (FOGM) process (amplitude, correlation time)
  - Use the  $\chi^2$  value for infinite averaging time predicted from this model to scale the white-noise sigma estimates from the original fit
  - and/or
  - Fit the values to a FOGM with infinite averaging time (i.e., random walk) and use these estimates as input to globk (mar\_neu command)

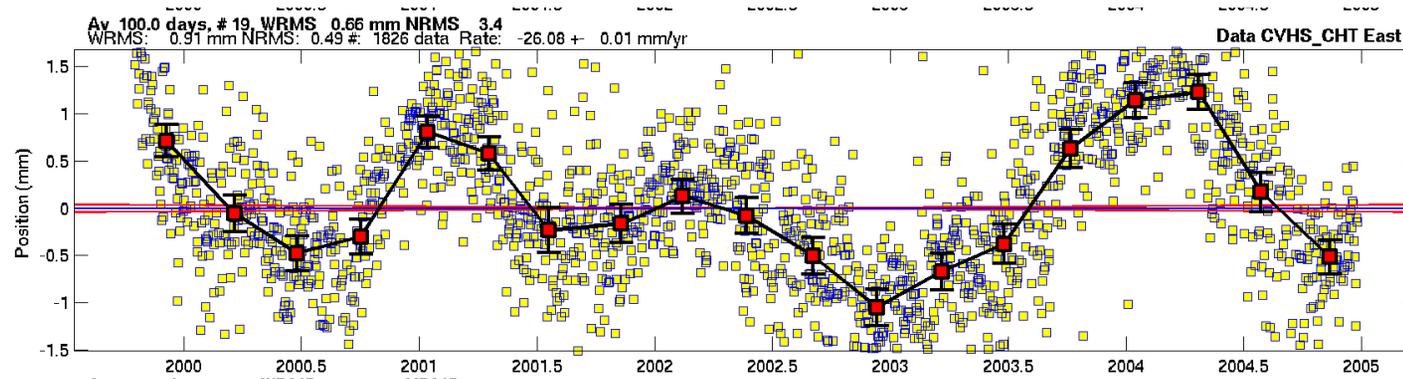

# Effect of Averaging on Time-series Noise

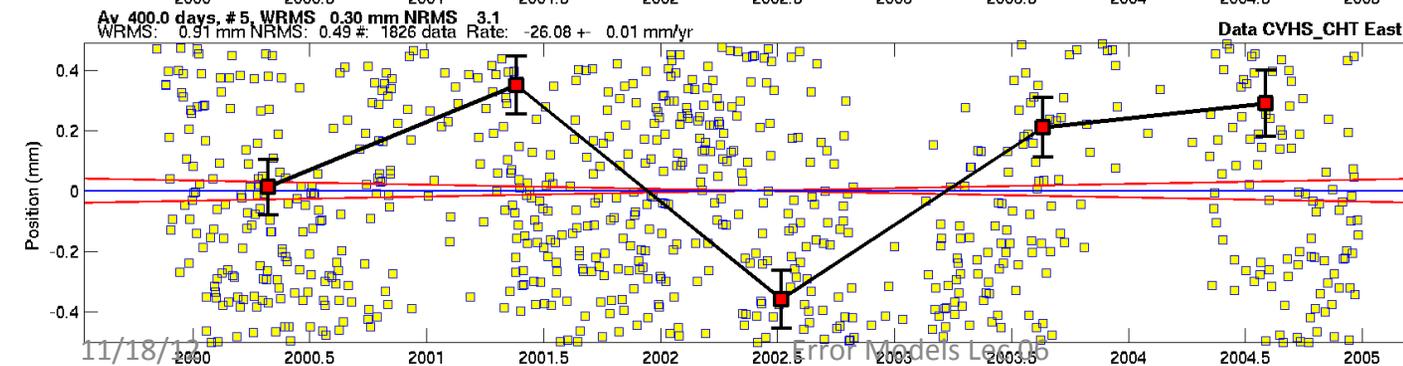

# Same site, East component ( daily wrms 0.9 mm nrms 0.5 )

64-d avg  
wrms 0.7 mm  
nrms 2.0

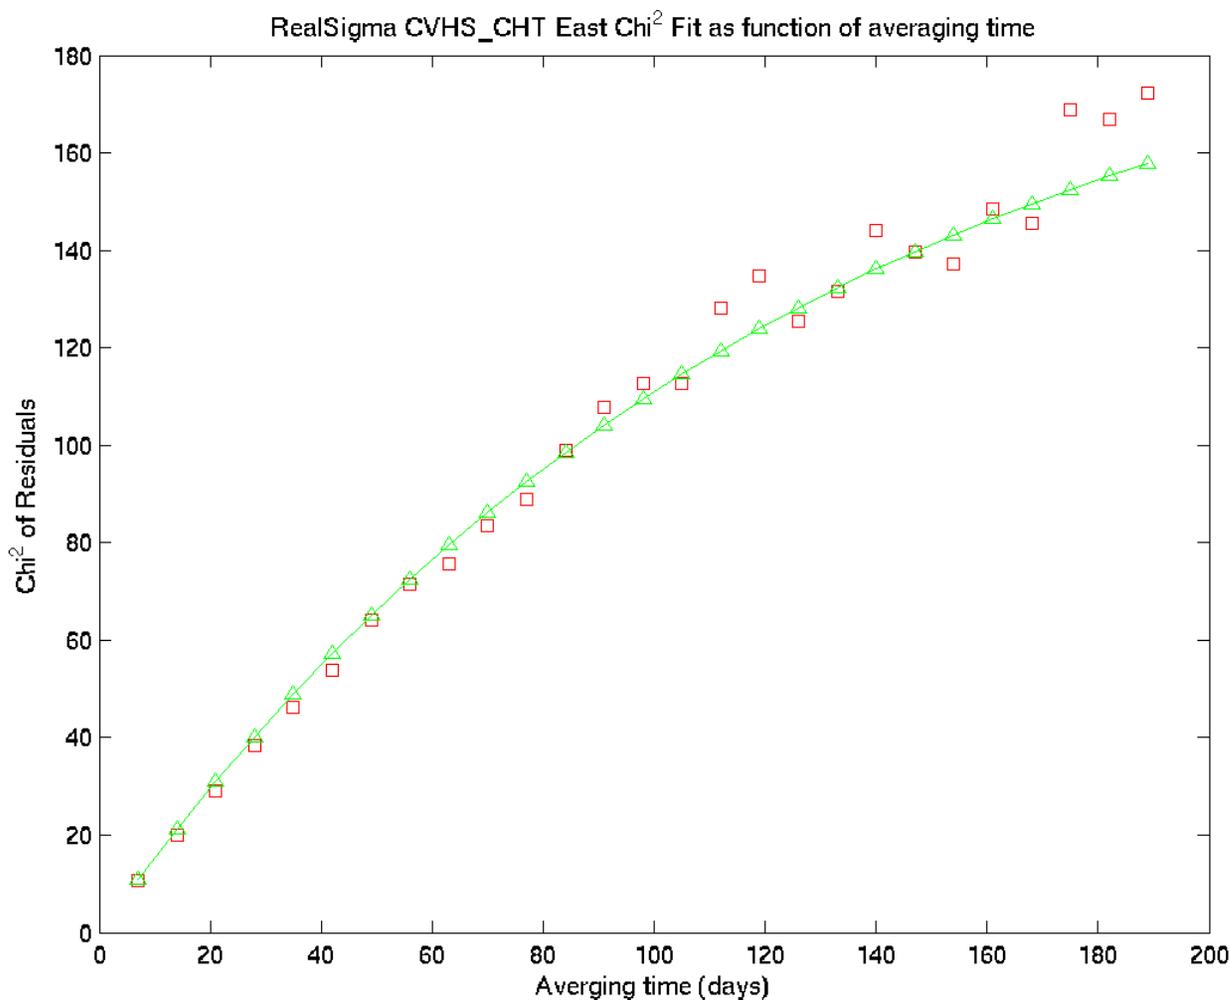

100-d avg  
wrms 0.6 mm  
nrms 3.4

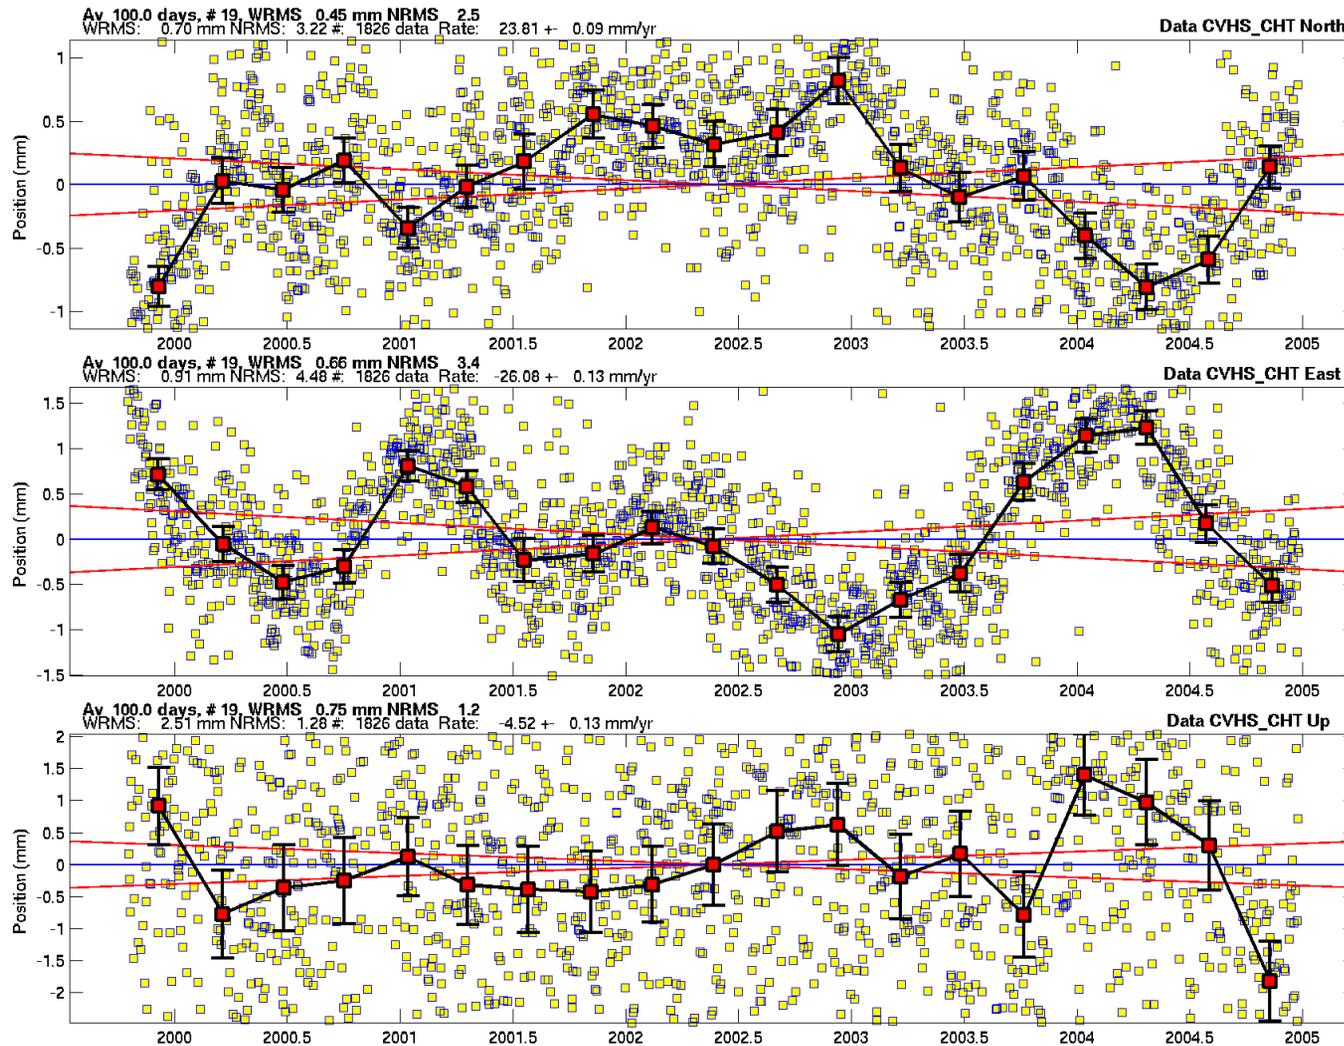

400-d avg  
wrms 0.3 mm  
nrms 3.1

# Estimating a “realistic-sigma” by fitting an exponential function to chi-square vs averaging time

Get scale factor by evaluating the function at an infinite averaging time

# Using TSVIEW to compute and display the “realistic-sigma” results

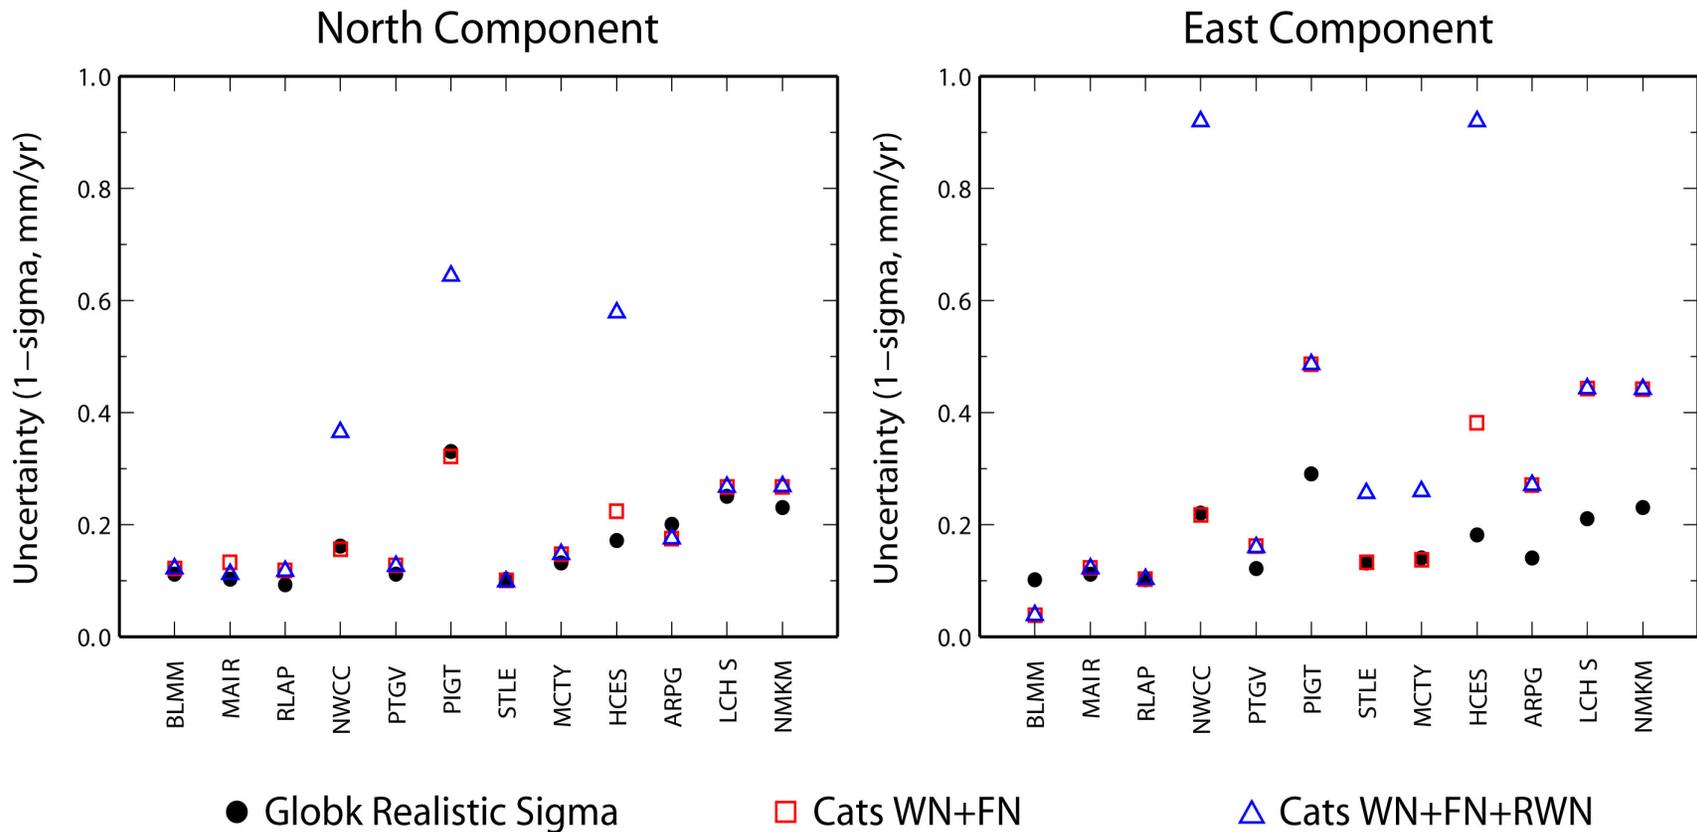

Note rate uncertainties with the “realistic-sigma” algorithm :

- 0.09 mm/yr N
- 0.13 mm/yr E
- 0.13 mm/yr U

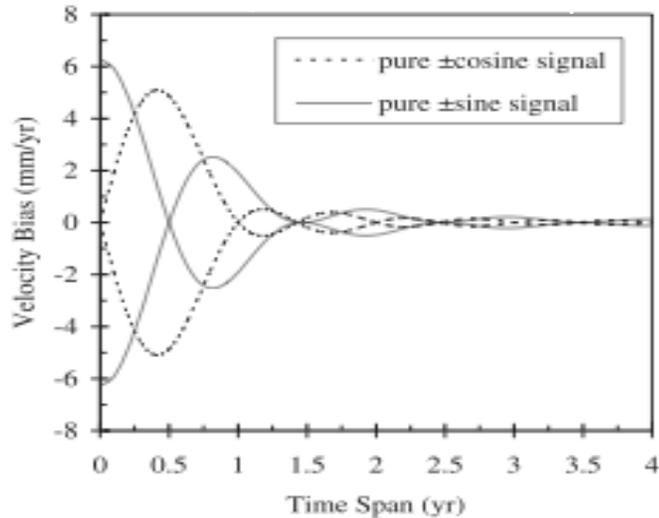

Red lines show the 68% probability bounds of the velocity based on the results of applying the algorithm.

# Comparison of estimated velocity uncertainties using spectral analysis (CATS\*) and Gauss-Markov fitting of averages (GLOBK)

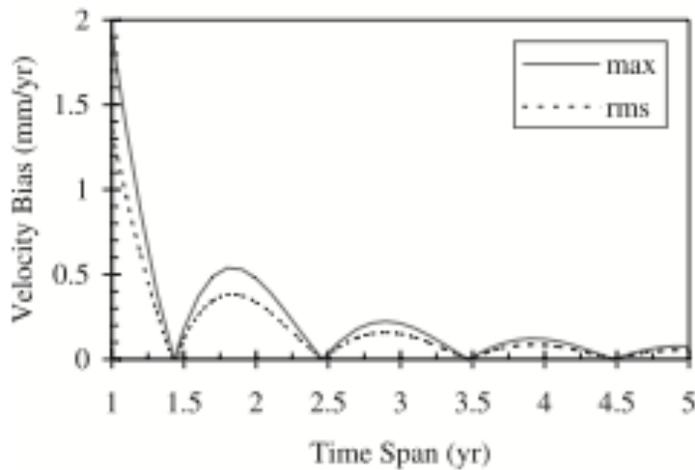

Plot courtesy E. Calias

# Velocity Errors due to Seasonal Signals

Theoretical analysis of a continuous time series by *Blewitt and Lavallee [2002]*

*Top:* Bias in velocity from a 1mm sinusoidal signal in-phase and with a 90-degree lag with respect to the start of the data span

*Bottom:* Maximum and rms velocity bias over all phase angles

- The minimum bias is NOT obtained with continuous data spanning an even number of years
- The bias becomes small after 3.5 years of observation

# Summary of Practical Approaches

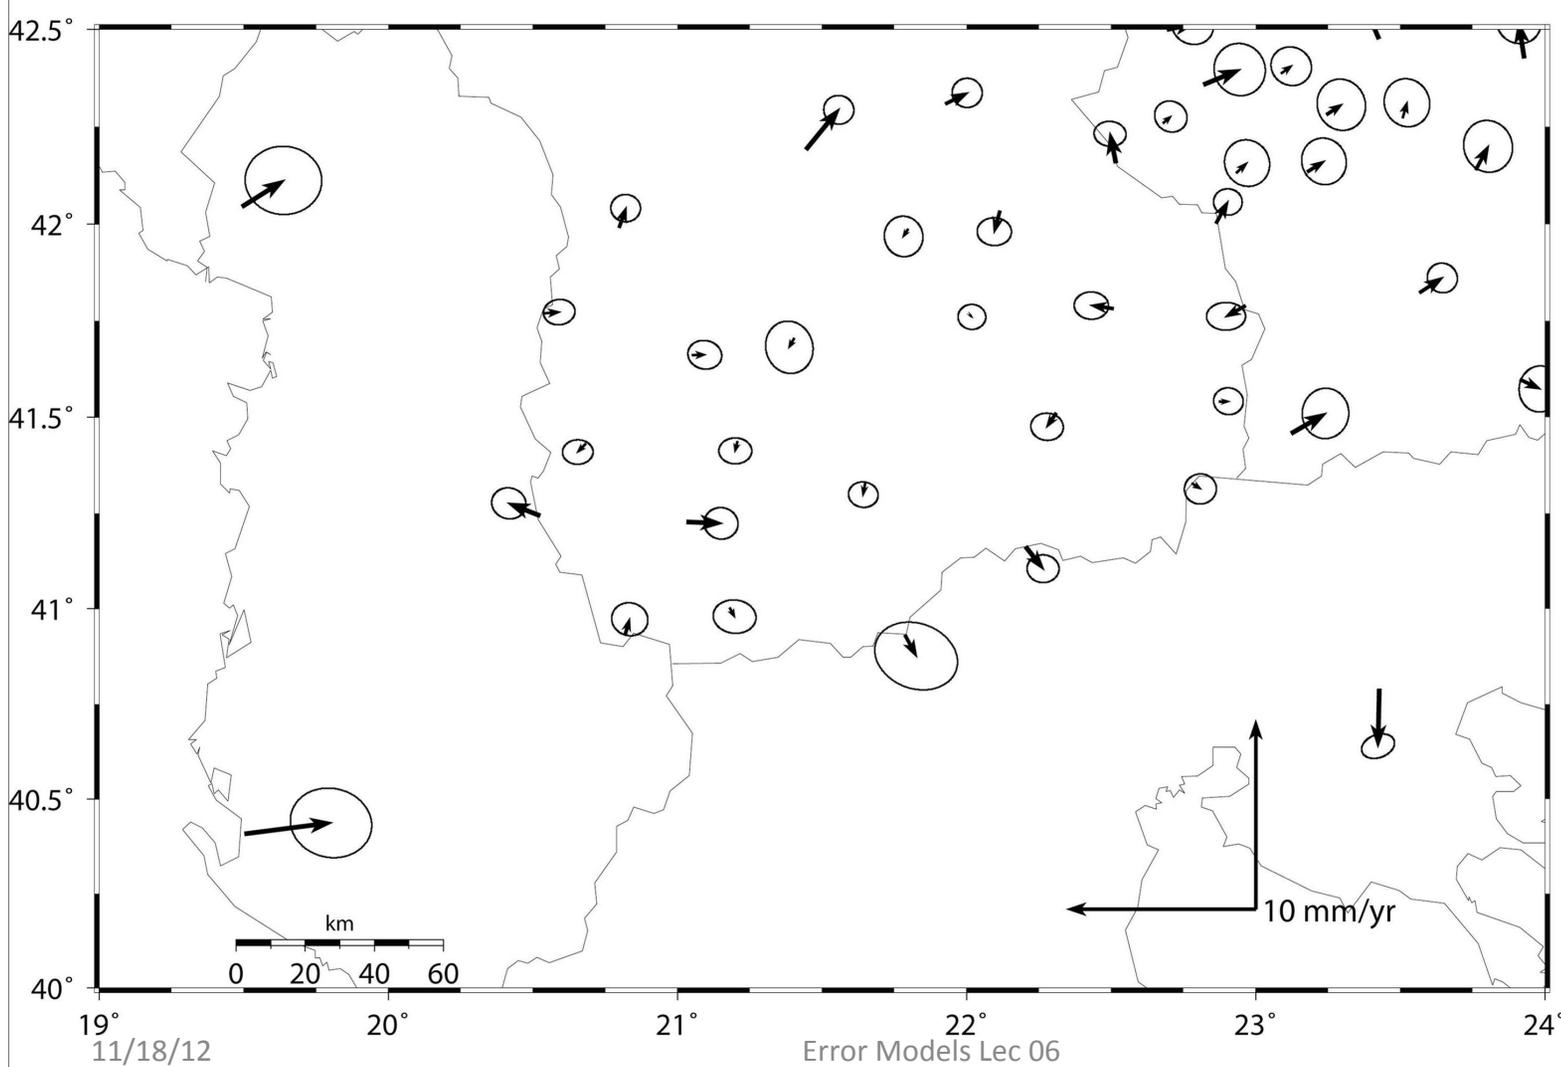

- White noise + flicker noise (+ random walk) to model the spectrum [Williams et al., 2004]
  - White noise as a proxy for flicker noise [Mao et al., 1999]
  - Random walk to model to model an exponential spectrum [Herring “realistic sigma” algorithm for velocities]
  - “Eyeball” white noise + random walk for non-continuous data
- 
- Only the last two can be applied in GLOBK for velocity estimation
  - All approaches require common sense and verification

# Determining the Uncertainties of GPS Estimates of Station Velocities

- Understanding the sources of error
- Time series analysis to determine statistics for reweighting the data
- Whatever the assumed error model and tools used to implement it, external validation is important

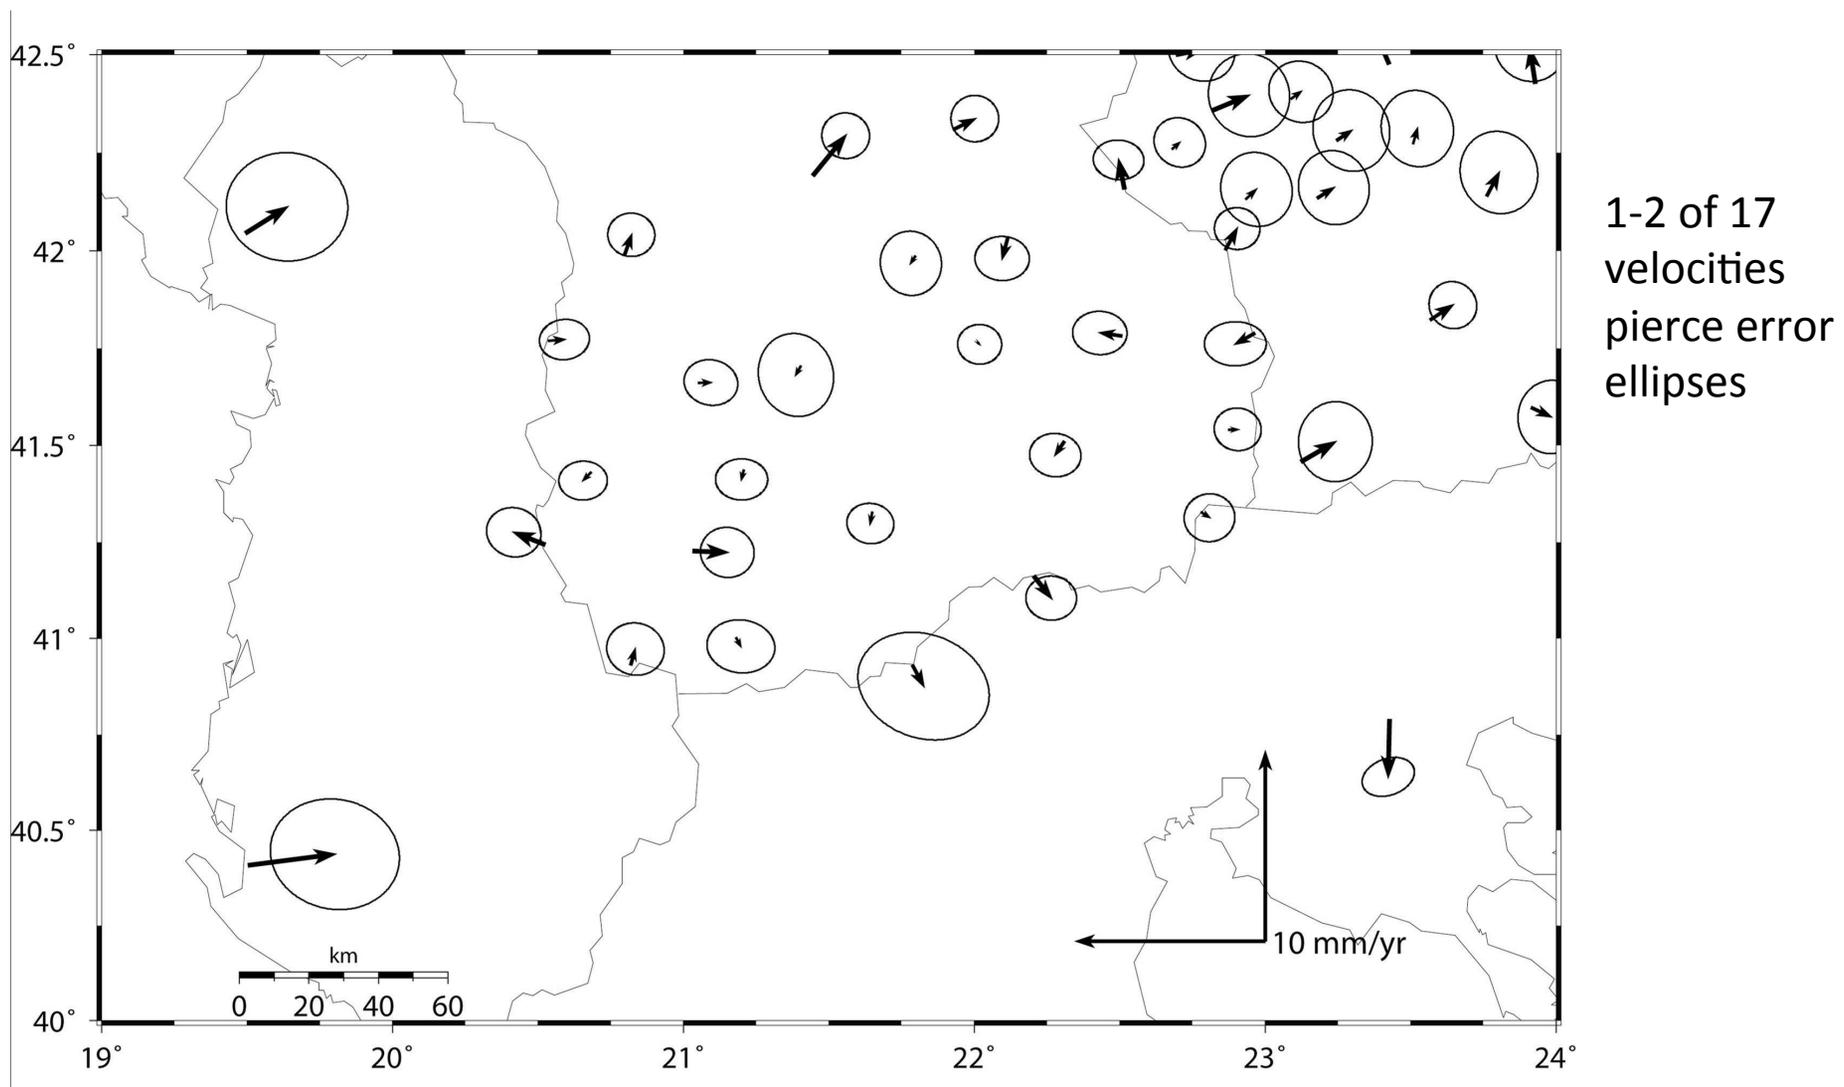

# External Validation for Velocity Uncertainties

-- assume no strain within a geological rigid block

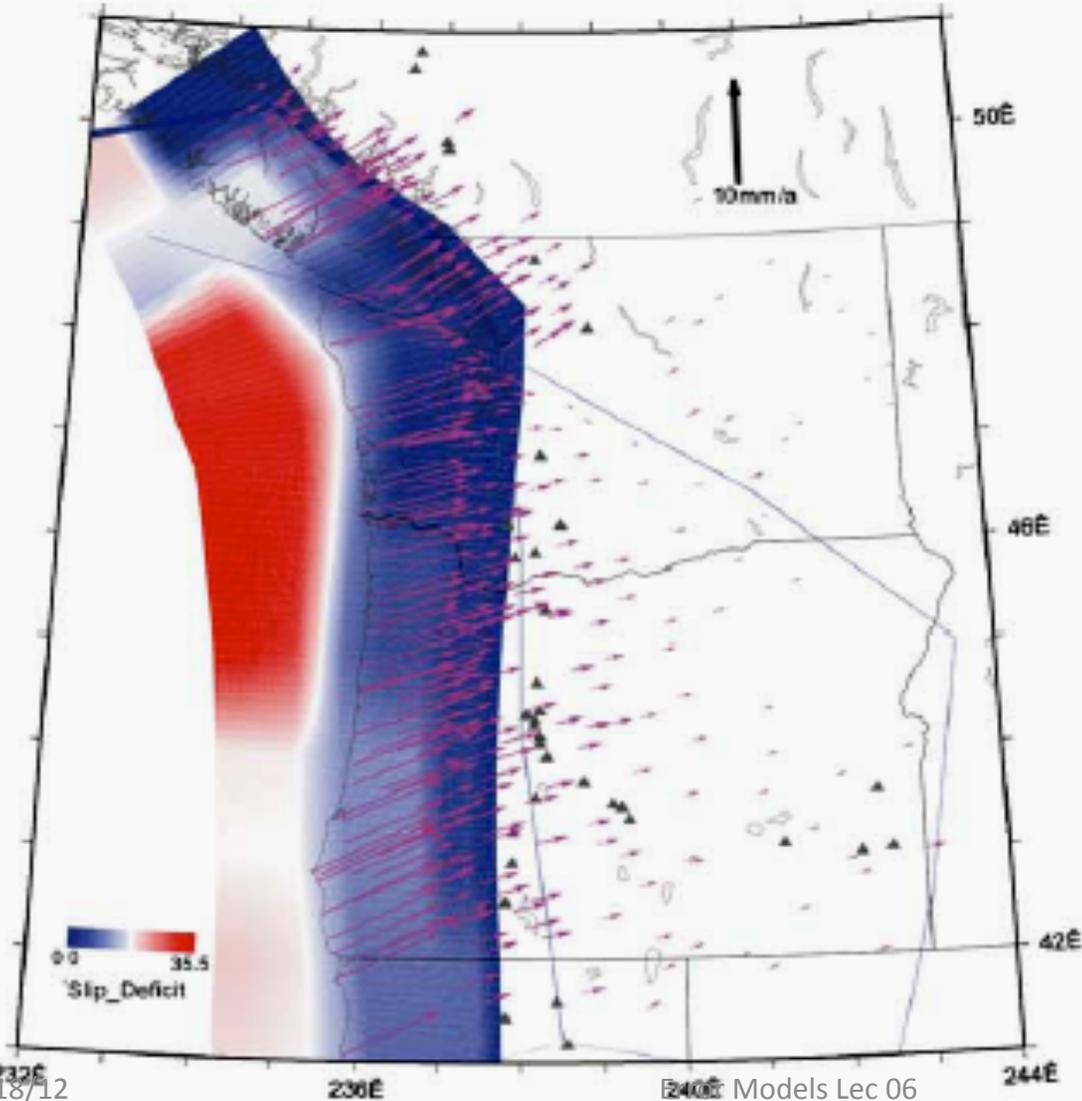

GMT plot at 70% confidence  
17 sites in central Macedonia:  
4-5 velocities pierce error ellipses

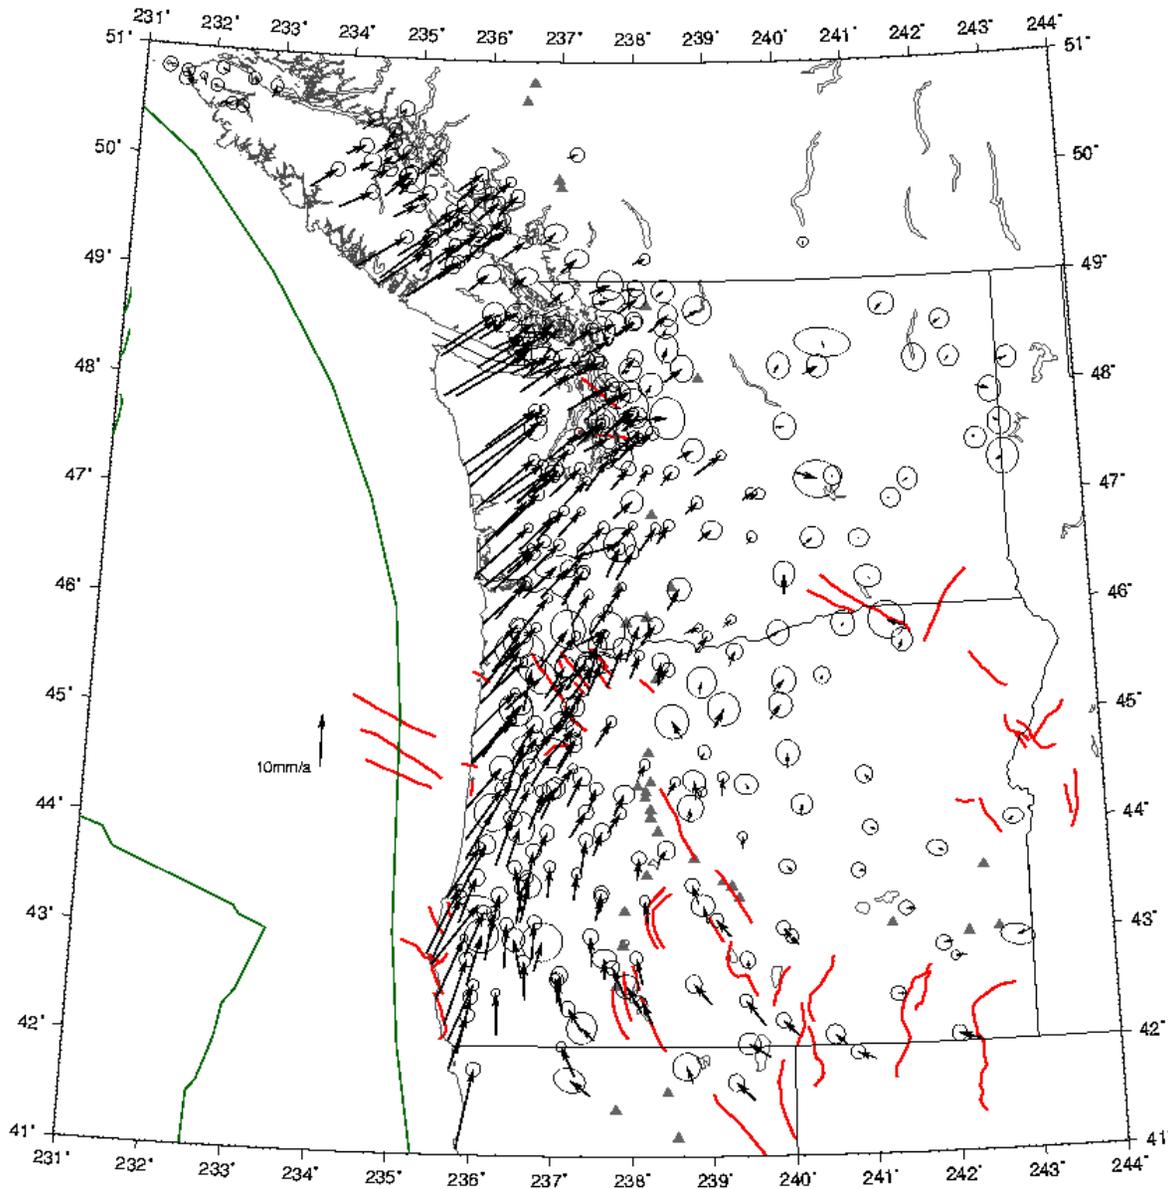

.. same solution plotted with 95% confidence ellipses

# A more rigorous assessment for data from Cascadia

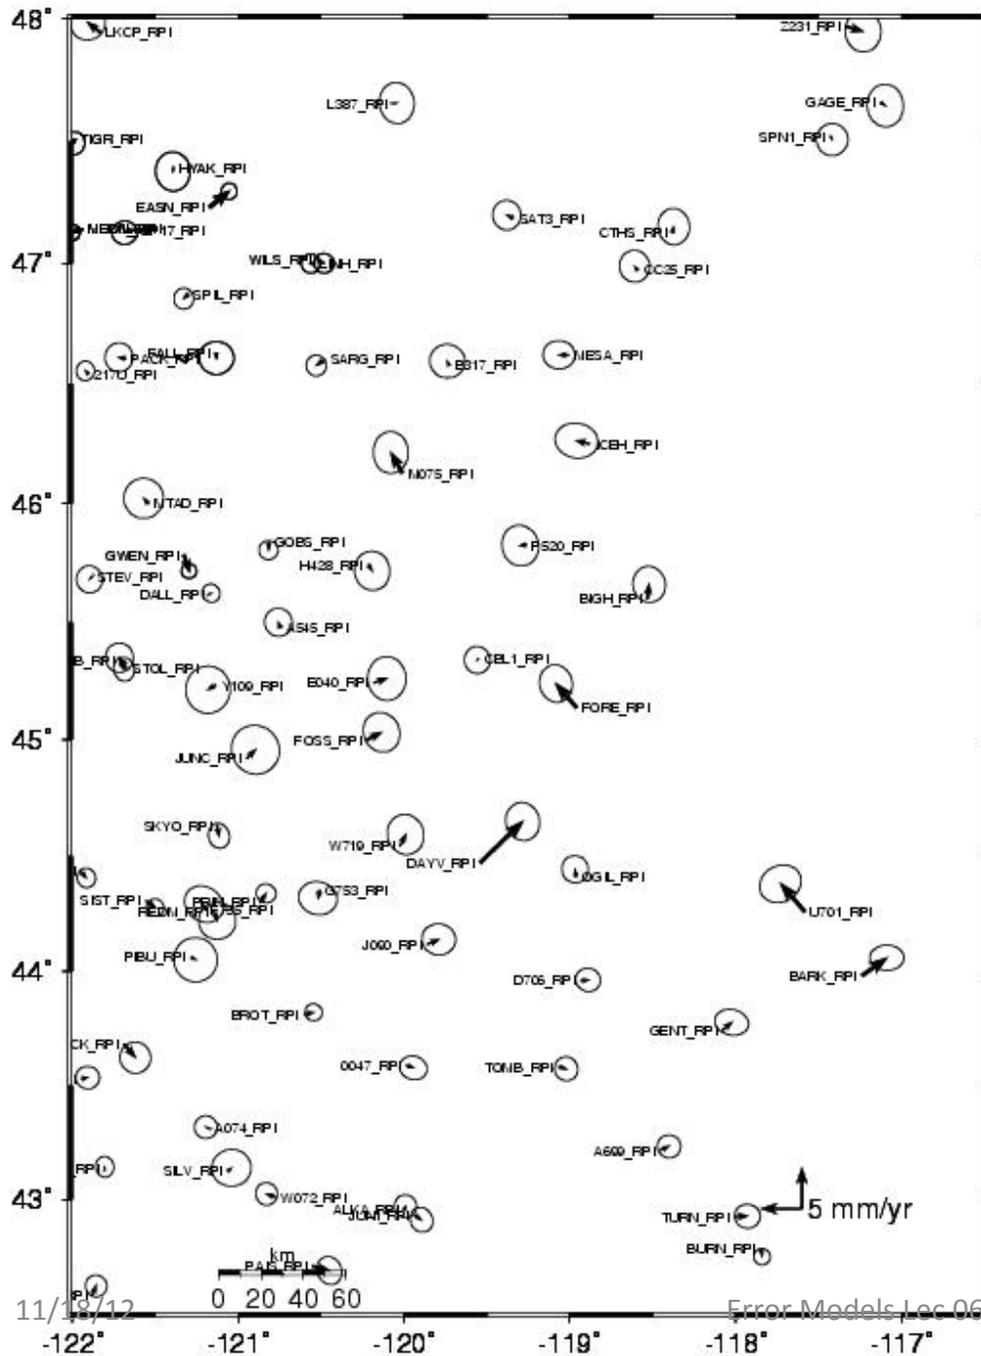

Colors show slipping and locked portions of the subducting slab where the surface velocities are highly sensitive to the model; area to the east is slowly deforming and insensitive to the details of the model

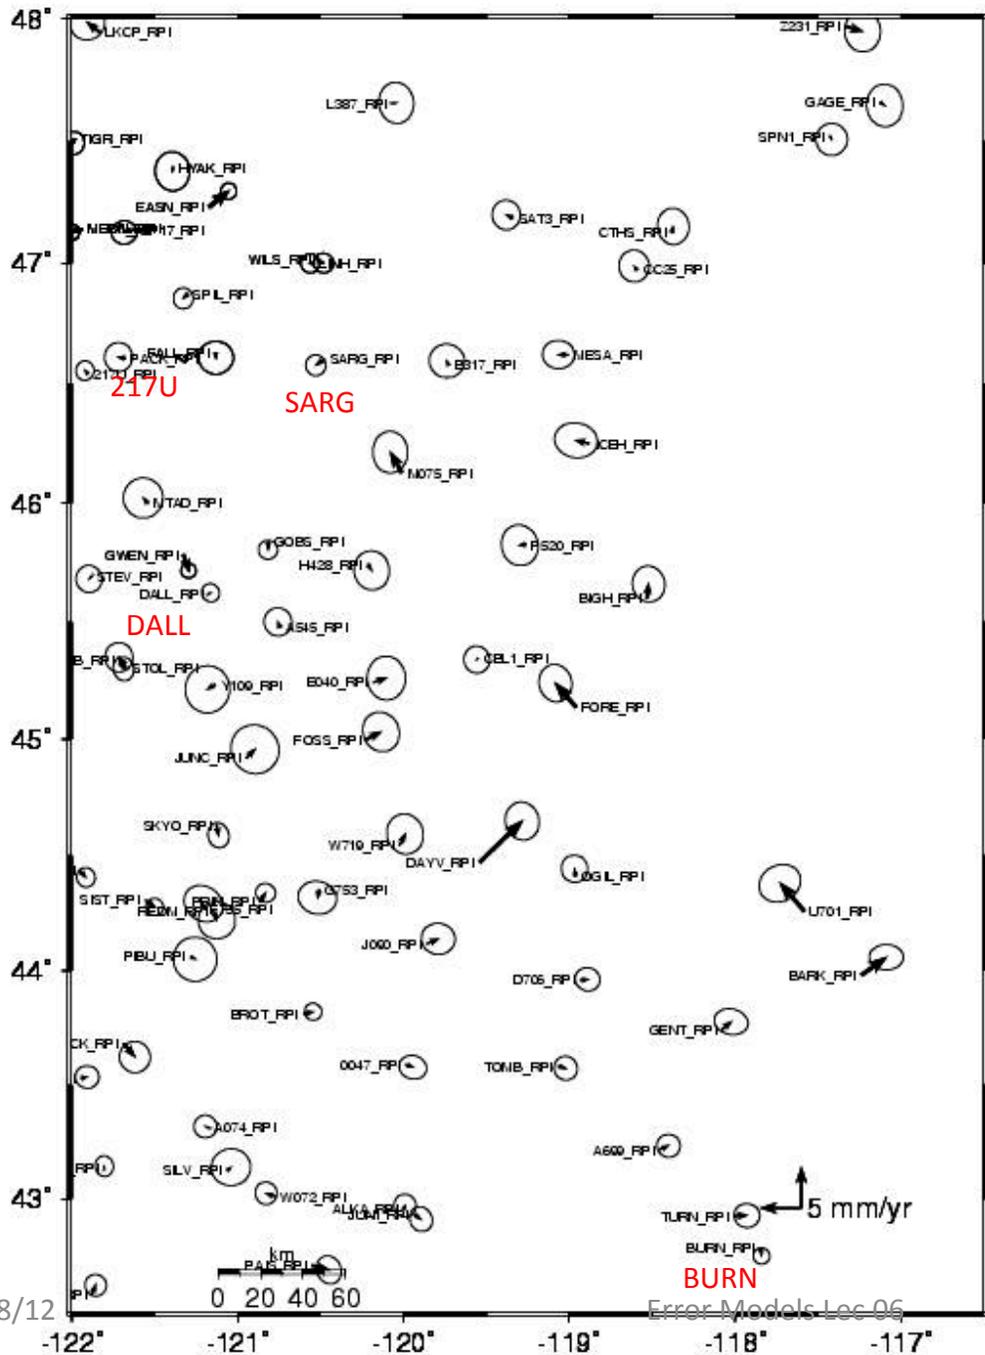

Velocities and  
70% error  
ellipses for 300  
sites observed by  
continuous and  
survey-mode  
GPS 1991-2004

Test area (next  
slide) is east of  
238E

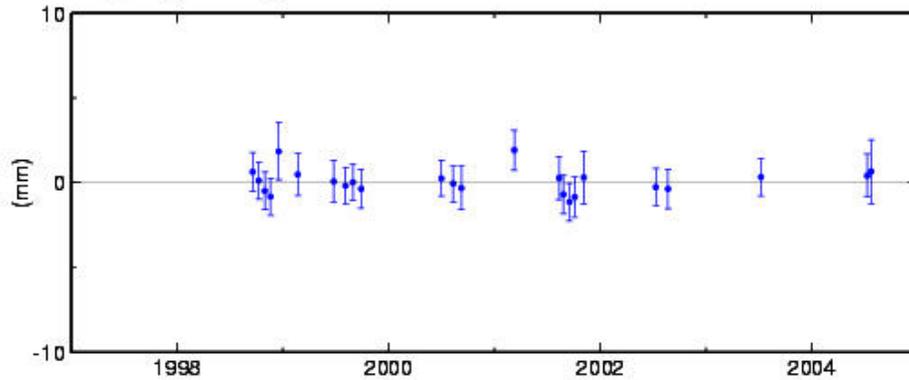

Residuals to elastic block model for 70 sites in slowly deforming region

Error ellipses are for 70% confidence:  
 13-17 velocities pierce their ellipse

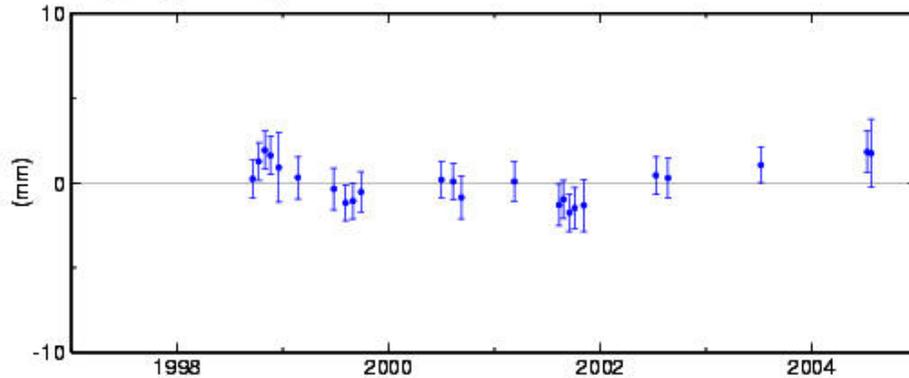

Locations of one continuous (BURN) and 3 survey-mode sites for time series shown in next slides

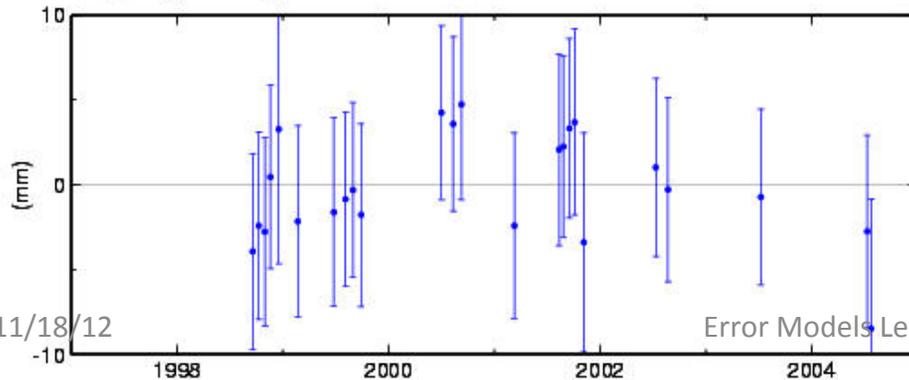

BURN North Offset 4762192.409 m  
rate(mm/yr)=  $0.88 \pm 0.15$  nrms= 0.59 wrms= 0.7 mm # 24

BURN East Offset 19785454.969 m  
rate(mm/yr)=  $-2.20 \pm 0.15$  nrms= 0.96 wrms= 1.1 mm # 24

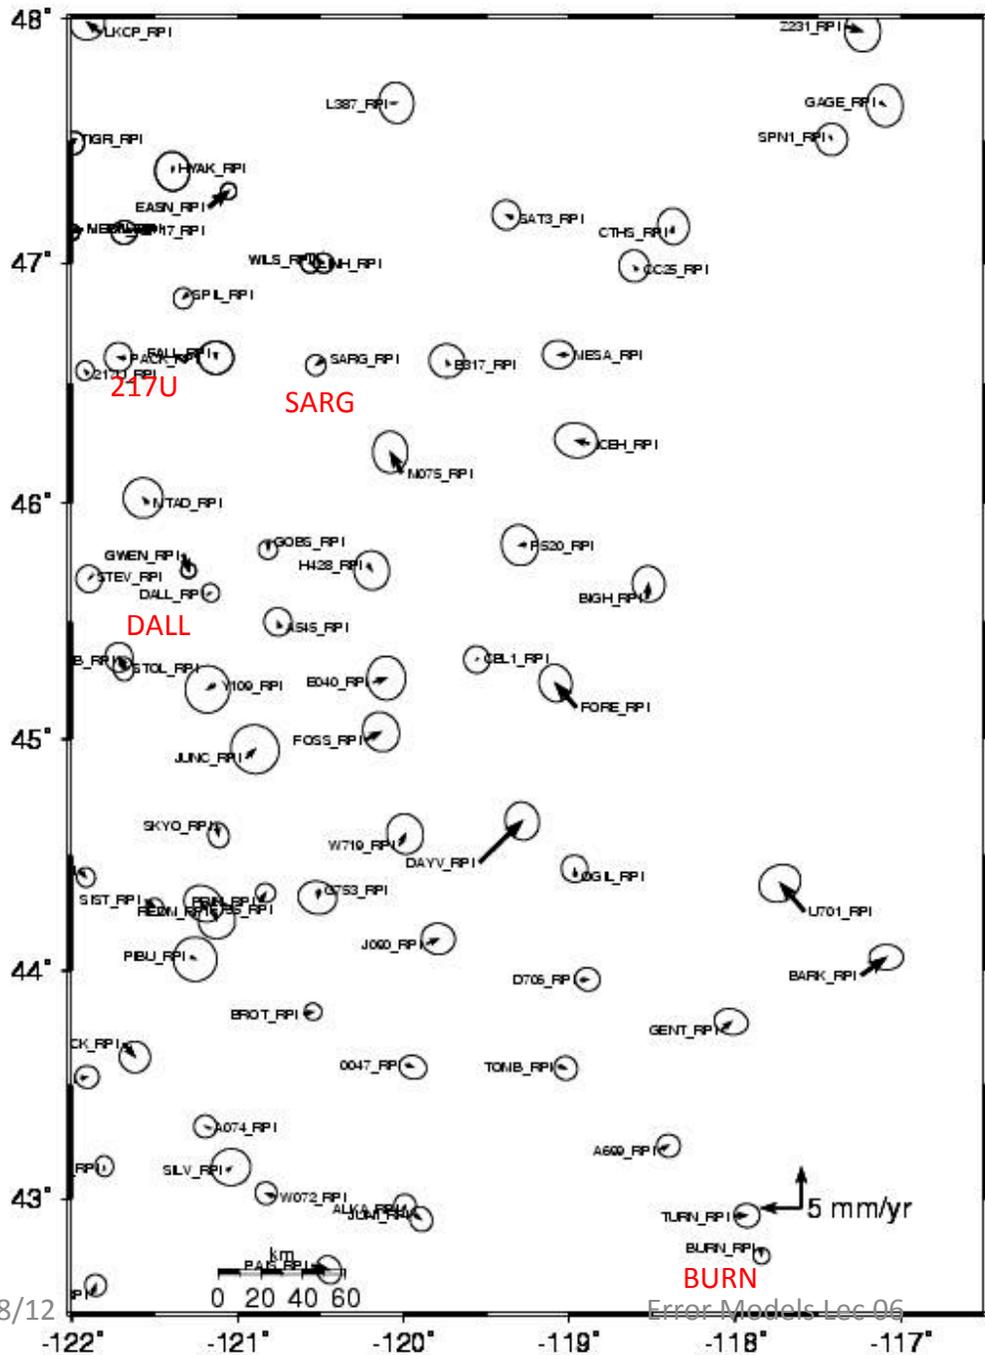

BURN Up Offset 1180.888 m  
rate(mm/yr)=  $-2.11 \pm 0.68$  nrms= 0.54 wrms= 3.0 mm # 24

Time series of monthly position estimates for continuous site BURN

Wrms ~ 1 mm N,E  
~ 3 mm U

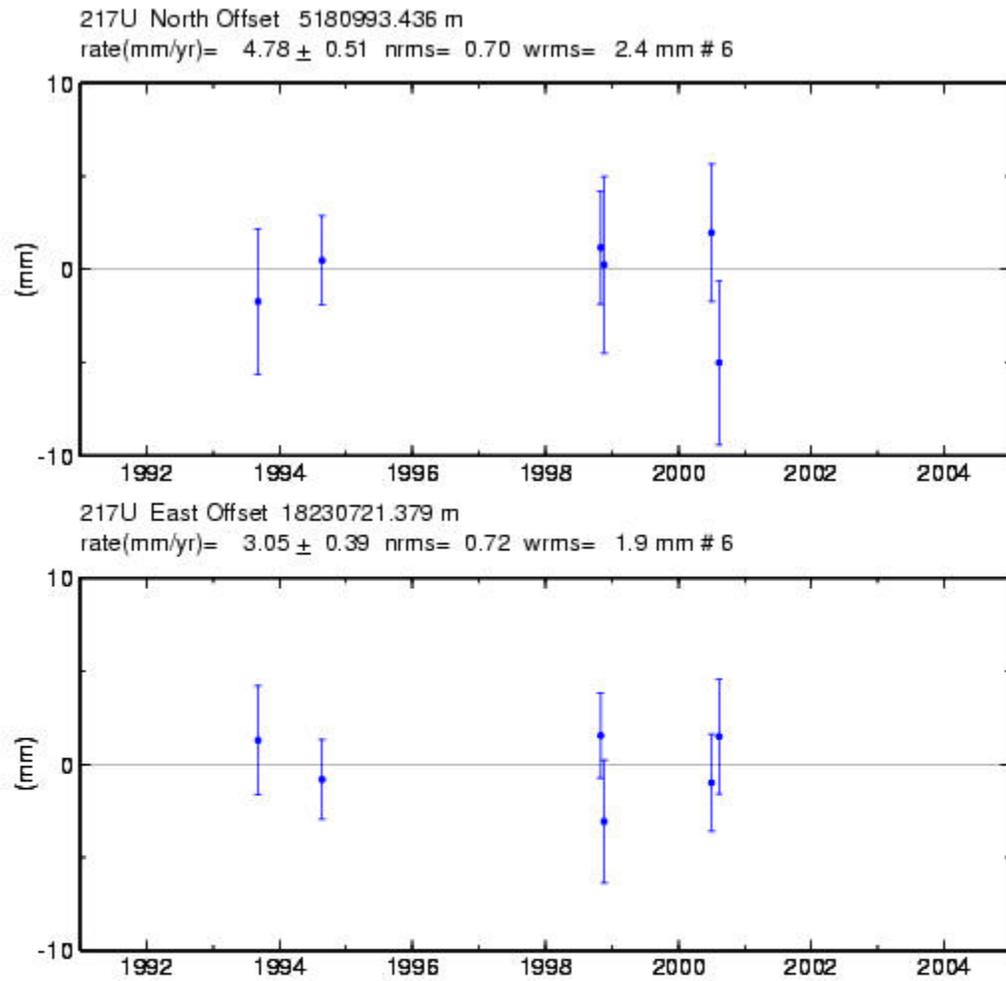

Rate uncertainties  
< 0.2 mm/yr N,E  
0.7 mm/yr U  
do not include random walk added for velocity estimates

Next slide shows time series for survey-mode site 217U

Note consistency with nearby sites

## Time series for survey-mode site 217U

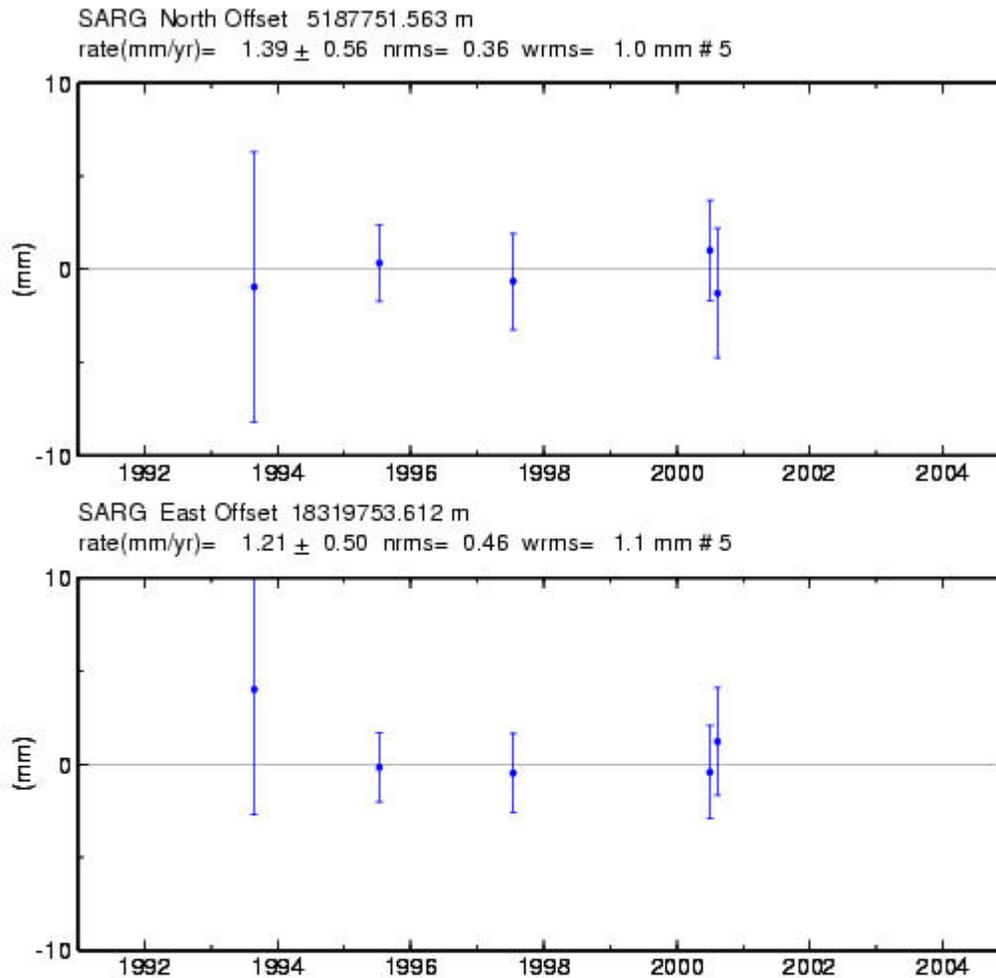

Position estimates based on 8-24 hr occupations

Note < 1 mm rate uncertainties due to 7-yr time span

## Horizontal time series for survey-mode site SARG

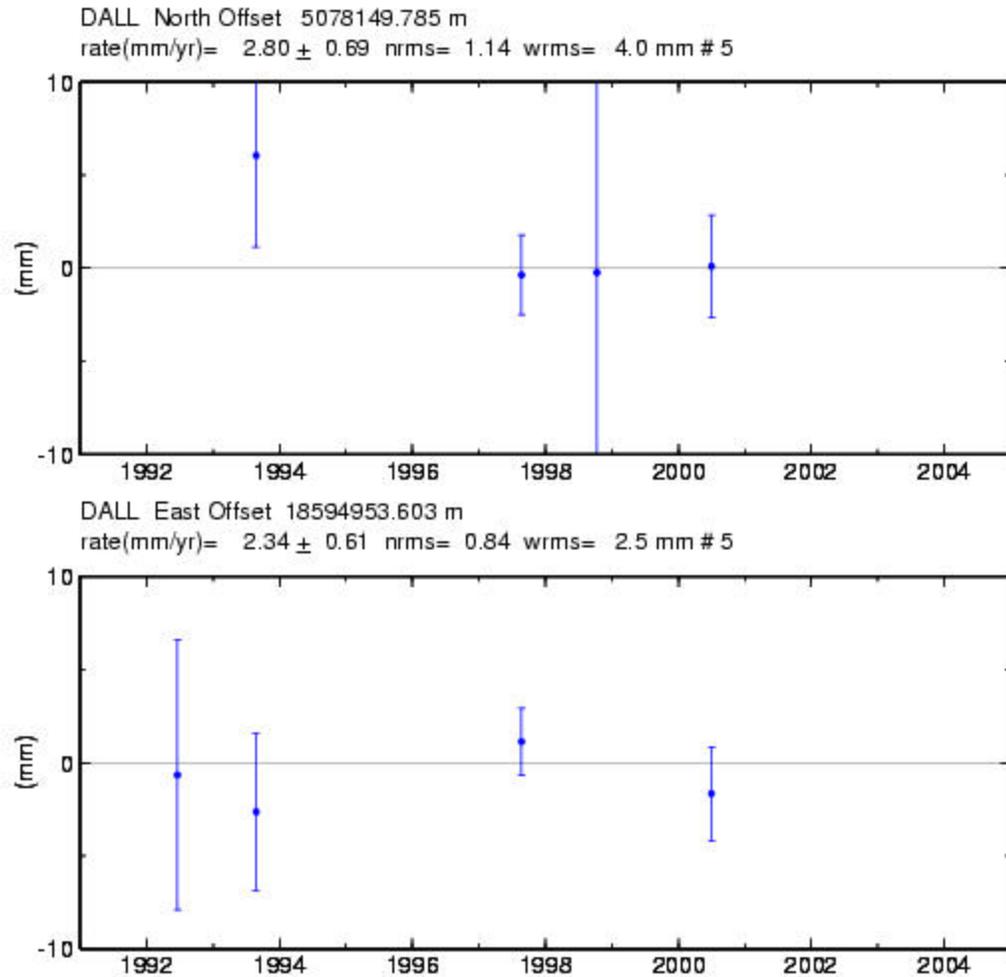

Position estimates  
based on 8-24 hr  
occupations

Note 1 mm wrms and  
< 1 mm rate sigmas

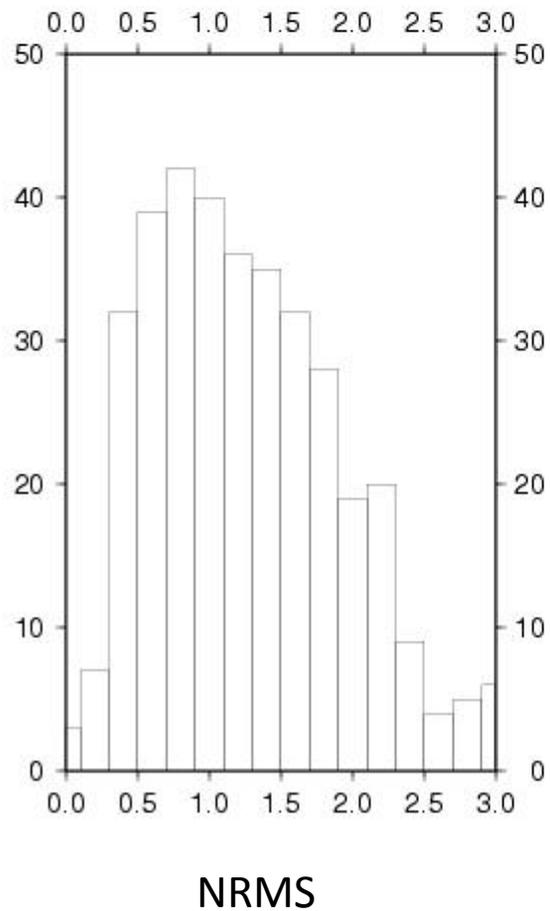

## Horizontal time series for survey-mode site DALL

Position estimates  
based on 8-24 hr  
occupations

Rate sigmas < 1 mm/yr  
and consistent with  
surrounding sites even  
with velocities  
determined essentially  
by two occupations 3  
yrs apart

## Statistics of Time Series

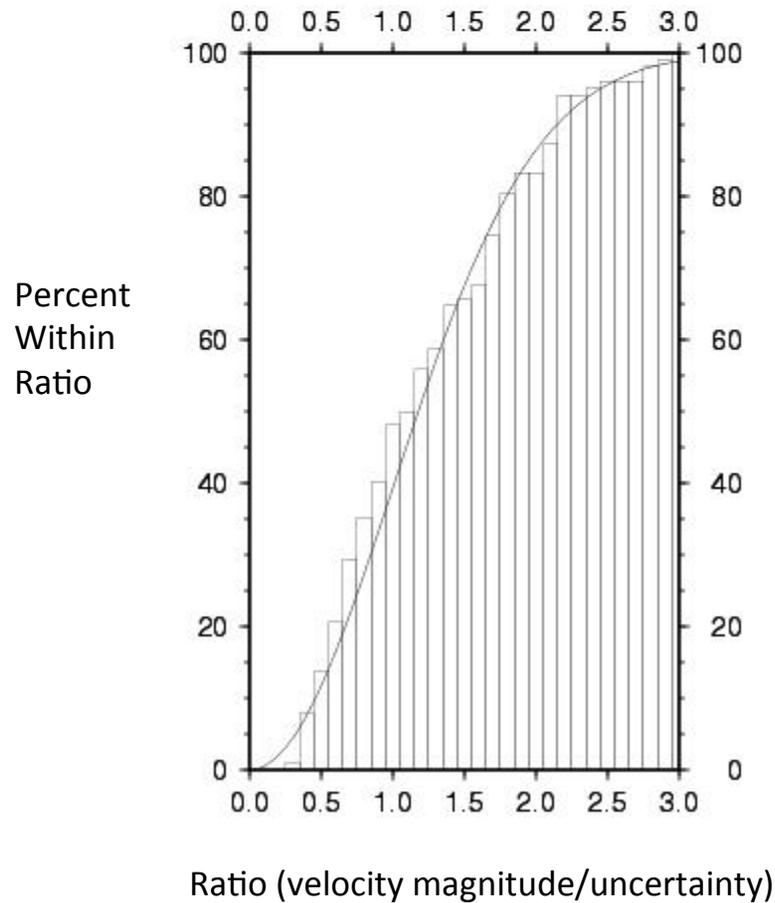

Distribution of normalized rms  
for horizontal magnitudes  
residuals after removing the  
block model

357 sites

NRMS

E, N 1.00, 1.03

## Statistics of Velocity Residuals

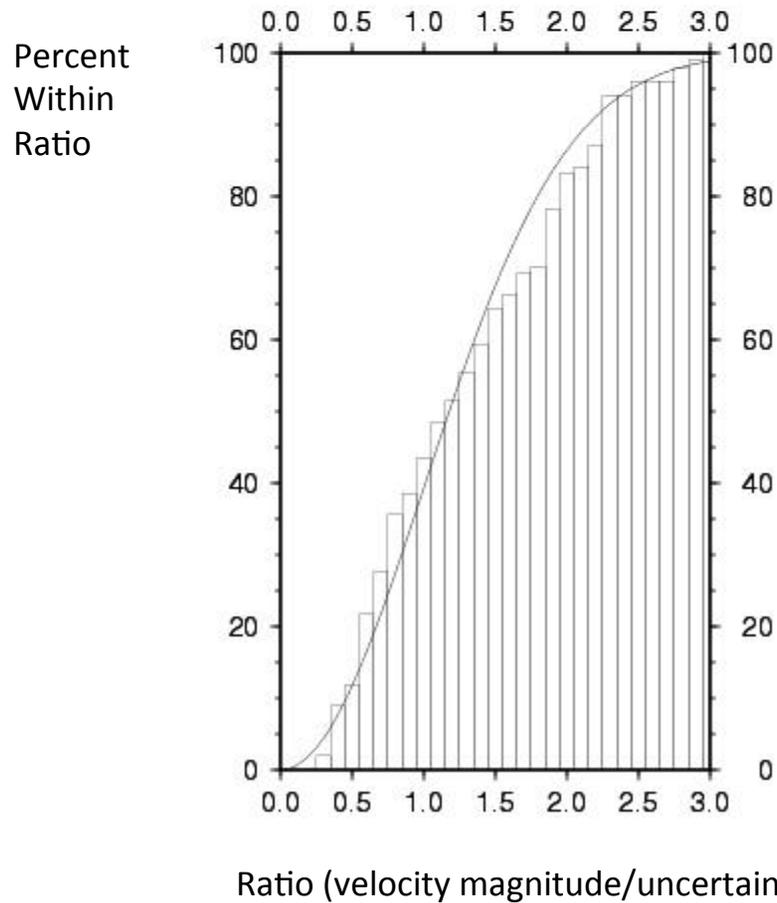

Cumulative histogram of normalized velocity residuals for Eastern Oregon & Washington ( 70 sites )

Noise added to position for each survey:  
0.5 mm random  
1.0 mm/sqrt(yr)) random walk

Solid line is theoretical for Gaussian distribution

## Statistics of Velocity Residuals

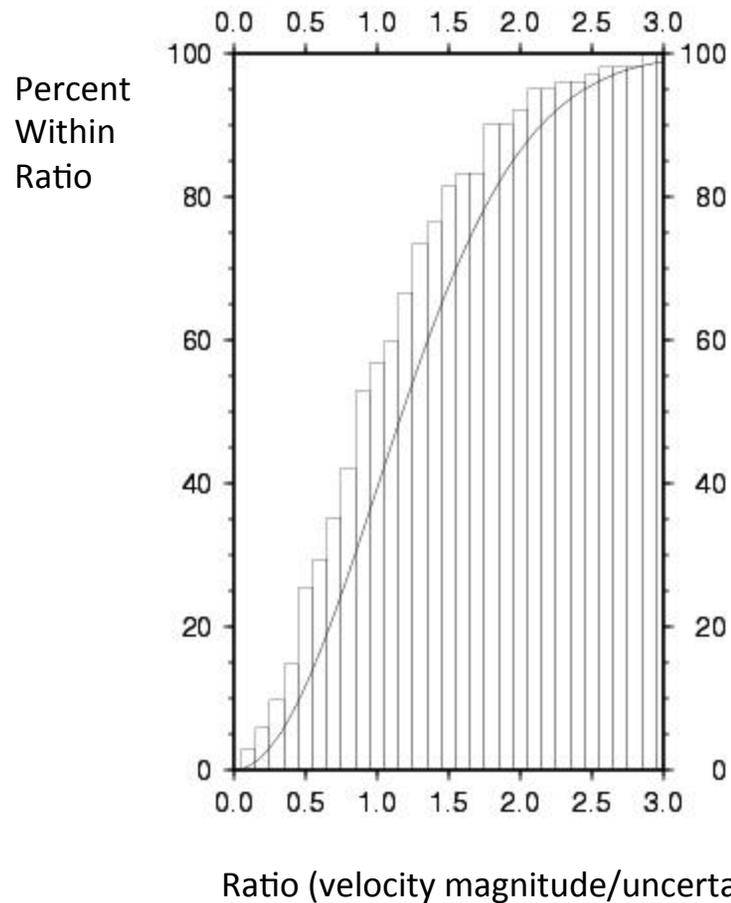

Same as last slide but with a smaller random-walk noise added :

0.5 mm random  
0.5 mm/yr random walk

( vs 1.0 mm/sqrt(yr)) RW for  
'best' noise model )

Note greater number of  
residuals in range of 1.5-2.0  
sigma

## Statistics of Velocity Residuals

Same as last slide but with larger random and random-walk noise added :

2.0 mm white noise  
1.5 mm/sqrt(yr) random walk

( vs 0.5 mm WN and 1.0 mm/sqrt(yr))  
RW for 'best' noise model )

Note smaller number of residuals in all ranges above 0.1-sigma

# Summary

- All algorithms for computing estimates of standard deviations have various problems: Fundamentally, rate standard deviations are dependent on low frequency part of noise spectrum which is poorly determined.
- Assumptions of stationarity are often not valid
- “Realistic sigma” algorithm is a convenient and reliable approach to getting velocity uncertainties in global
- Velocity residuals from a model, together with their uncertainties, can be used to validate the error model

# Tools for Error Analysis in GAMIT/GLOBK

- GAMIT: AUTCLN reweight = Y (default) uses phase rms from postfit edit to reweight data with constant + elevation-dependent terms
- GLOBK
  - rename ( eq\_file) \_XPS or \_XCL to remove outliers
  - sig\_neu adds white noise by station and span; useful for handling outliers
  - mar\_neu adds random-walk noise: principal method for controlling velocity uncertainties
  - In the gdl files, can rescale variances of an entire h-file: useful when combining solutions from with different sampling rates or from different programs (Bernese, GIPSY)
- Utilities
  - Realistic sigma” algorithm implemented in tsview (MATLAB) and enfit/ensum; sh\_gen\_stats generates mar\_neu commands for globk based on the noise estimates
  - sh\_plotvel (GMT) allows setting of confidence level of error ellipses
  - sh\_tshist and sh\_velhist can be used to generate histograms of time series and velocities.

# Summary

- There are no absolute methods that ensure the correct error model can be determined for a set of data processing.
- We attempt to determine with 1-sigma values, that 68% of values will be within this range due to noise; with 2-sigma, 95% of values (1-d) even when the probability distribution is not Gaussian.
- The most under certain aspect is determining the nature of the temporal and spatial correlations in the results. Generally, large amounts of data are needed for this and the assumption of stationarity.
